ABSTRACT

Mesenchymal Stromal/Stem (MSCs) cells possess a remarkable capacity as a therapeutic option for many diseases. These cells have immunomodulatory, proangiogenic, regenerative and anti-inflammatory capabilities. In spite of possessing such capabilities, these cells behave differently in the in-vivo environment in the diseased condition, and in many instances lose their therapeutic potential. This case report presents evidence about empowerment of MSCs from a pregnant woman who underwent a set of yogic exercises during her pregnancy. MSCs isolated from this woman were found to be in a better state post-cryopreservation, and also while mediating their immunomodulatory effect.

Introduction

Mesenchymal stem/stromal cells (MSCs) exhibit various properties like self-renewal capacity, multilineage differentiation, angiogenesis and immunomodulatory properties. These features make them an extremely promising tool for translational research and clinical applications. MSCs are found in various adult tissues and the cues in the micro niche dictate their fate and function (1,2). It is known that various categories of exercises can affect the extracellular matrix composition, inflammatory milieu, and such changes in the niche lead likely to the alteration of tissue-specific stem cell populations and their functions post-exercise (3–5). The clinical application strategies of mesenchymal stem cells are still evolving, and in spite of their extra ordinary properties, the deployment of MSCs is not completely reflected in the clinical trials (6).

The requirement of the MSCs to be cultured in vitro for upto 3–4 weeks for their cultivation and expansion may be a deterrent to the realization of some of their biological functions. Furthermore, harsh environment in vivo post-injection in the recipient in its diseased state leads to them having shorter life-span (7). Licensing and optimization of MSC culture conditions are key strategies to improving the MSC functions in vitro and in vivo. All of these procedures reportedly contribute to enhancing the MSC transplantation efficacy in tissue engineering and regenerative medicine (8).

In this report, we have analysed the MSCs from the Wharton’s jelly of a yoga-practising woman and found them to be possessing better properties. If tested and proved to be working in cells isolated from a larger sample size of yoga-practising pregnant women, such MSCs might be more effective when used for therapeutic purposes.

Yoga Protocol

The mother practised the yoga exercises as per (Table 1).

**Case Presentation**

**Isolation of Mesenchymal Stromal Cells**

Human umbilical cord tissue was taken from the full-term birth of patient P1 from the Department of Obstetrics & Gynecology, PGIMER, Chandigarh (The patient’s consent was obtained and the respective approvals were taken from Institute ethics committee and Institute stem cell committee). P1 was 27 years in age and had no history of chronic infectious disease, STD or hepatitis. MSCs were isolated from the Wharton’s jelly (WJ-MSCs) from the umbilical cord tissue using standardized explant method. WJ pieces were washed with Phosphate-Buffered Saline (PBS), seeded in T-25 flasks and cultured in complete α-Minimum Essential Medium (Sigma Aldrich). Cells were kept in an incubator with 5% CO₂ at 37°C. After 70–80% confluence was achieved, cells were trypsinized and expanded till required passage number 2.

**Characterization of MSCs**

MSCs were characterized both phenotypically and functionally in accordance with the International Society for Cell Therapy (ISCT) guidelines (9). MSCs were phenotyped for standard markers including CD34, CD45, CD11b, CD19, HLA-DR, CD73, CD90, and CD105 (BD Stemflow Human MSC Analysis Kit) through flow cytometry (BD FACS ARIA II). Cell count and viability were determined by staining with the Annexin-V kit (Sigma Aldrich), as per manufacturer’s protocol. Cells negative for annexin V and Propidium Iodide were counted and recorded as the viable population. MSCs were assessed for their multilineage differentiation potential to adipocyte, chondrocyte and osteogenic lineage.

**Cryopreservation of MSCs**

MSCs were cryopreserved in 10% Dimethyl Sulphoxide (DMSO) [Sigma Aldrich™] and 90% Fetal Calf Serum (FCS) [LONZA™] at 1°C/min cooling rate and stored in liquid nitrogen the following day. Their viability was analysed after 2 months.

**Immunomodulatory Capacity of MSCs**

Following the cryopreservation of two months, MSCs were analysed for their immunomodulatory capacity in a mixed lymphocyte reaction (MLR). CFSE (carboxyfluorescein succinimidyl ester) [Thermofisher Scientific™] labelled responder cells (peripheral blood mononuclear cells - PBMCs) were co-culture with mitomycin inactivated stimulator cells at a cell number of 0.3 × 10⁶ for each to induce lymphocyte proliferation. Unprimed MSCs (Control MSCs) or yoga-conditioned MSCs (Y-MSCs) were added to the MLR at a 1:10 ratio (MSC:PBMC). Co-cultures were incubated for four days at 37°C in a CO₂ incubator, before analysing the proliferation of PBMCs in the cultures. The cell proliferation was analysed by acquiring the cells in flow cytometry and proliferation index was determined using Flowjo software.

MSCs stained with fluorochrome labelled antibodies showed >95% positivity for CD73, CD90 and CD105 in both control MSCs (C-MSCs) and Y-MSCs (Figure 1). The pattern of both C-MSCs & Y-MSCs was similar for adipogenic, chondrogenic and osteogenic differentiation abilities.

Interestingly, post cryopreservation the viability of Y-MSCs was 96% as compared to 82% viability of C-MSCs (Figure 2). Moreover, the proliferation index of PBMCs was significantly reduced in Y-MSCs group when compared to the unprimed group (Figure 3).

**Discussion**

Physical exercise and yogic kriyas have known beneficial effects on overall healthy being. Considering the cellular level, endogenous MSCs contribute to tissue homeostasis but are largely insufficient in case of severely damaged tissues. Therefore, developing MSC therapeutics holds great promise for the regeneration and immune modulation for various disease conditions. They display unique immunomodulatory properties due to the paracrine factors secreted by them (10).
However, the complete efficacy of MSCs is not reflected adequately in terms of their clinical usage, and various regimens are being tried to license them to be functionally stable and more effective. They perform better if preconditioned in tailor made conditions according to the pathophysiology of the targeted diseased condition (11). Furthermore, for off-shelf supply, these cells have to be cryopreserved for on-demand availability. With the goal of understanding if yoga potentiates the capabilities of MSCs, this study was designed to understand the effect of cryopreservation on yoga-primed MSCs in terms of their viability and immunomodulation functional capacity. Various form of exercises have been reported to influence the biological properties of MSCs in various model systems (12–15), including their immunomodulation. Taken together, the results from our study provide a proof of concept indicating two significant findings which contribute to understanding the role of yoga in modulating properties of MSC. We propose that on account of having practiced a set of yoga exercises, the Y-MSCs revive in a better way with higher viability and, that the Y-MSCs become more potent immunomodulators.

**Conclusion**

This study forms a platform for testing the hypothesis in characterising WJ-MSCs from a larger cohort of yoga-practising pregnant women having genetic heterogeneity, and has implications in addressing pertinent issue of data gaps in the upcoming scientific field of evidence-based traditional medicine.

**Authors' contribution**

D: Performed the experimental part and collected the sample; PN: Conducted Yoga Intervention in the Pregnant Women; AR: Conceived the idea, and guided the experimental plan.
Informed consent
The study was verbally explained to the patient and written consent was signed by the patient.
